COMP 204

Algorithm design: Linear and Binary Search

Mathieu Blanchette
based on material from Yue Li, Christopher J.F. Cameron and Carlos G. Oliver

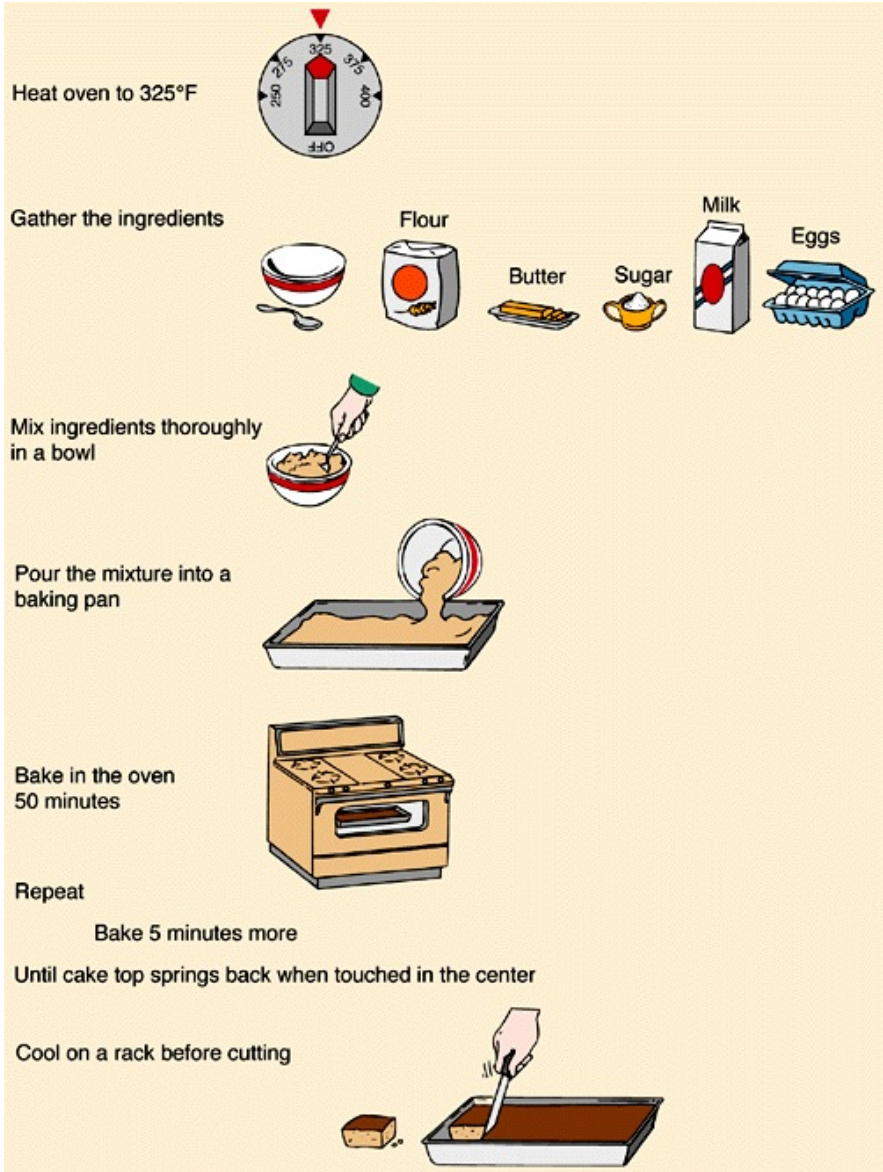
Algorithms

An **algorithm** is a predetermined series of instructions for carrying out a task in a finite number of steps

- or a recipe

Input $\rightarrow$ algorithm $\rightarrow$ output

Example algorithm: baking a cake



What is the input?

algorithm?

output?

Pseudocode

Pseudocode is a universal and informal language to describe algorithms from humans to humans

It is not a programming language (it can't be executed by a computer), but it can easily be translated by a programmer to any programming language

It uses variables, control-flow operators (while, do, for, if, else, etc.)

Example Python statements

```
1  students = ["Kris", "David", "JC", "Emmanuel"]
2  grades = [75, 90, 45, 100]
3  for student, grade in zip(students, grades):
4      if grade >= 60:
5          print(student, "has passed")
6      else:
7          print(student, "has failed")
8  #output:
9  #Kris has passed
10 #David has passed
11 #JC has failed
12 #Emmanuel has passed
```

Example pseudocode

Algorithm 1 Student assessment

```
1: for each student do
2:     if student's grade ≥ 60 then
3:         print 'student has passed'
4:     else
5:         print 'student has failed'
6:     end if
7: end for
```

Search algorithms

Search algorithms locate an item in a data structure
Input: a list of (un)sorted items and value of item to be searched

Algorithms: linear and binary search algorithms will be covered

- images if search algorithms taken from: `http://www.tutorialspoint.com/data_structures_algorithms/`

Output: if value is found in the list, return index of item
Example:

- search (key = 5, list = [3, 7, 6, 2, 5, 2, 8, 9, 2]) should return 4.
- search (key = 1, list = [3, 7, 6, 2, 5, 2, 8, 9, 2]) should return nothing.

Linear search

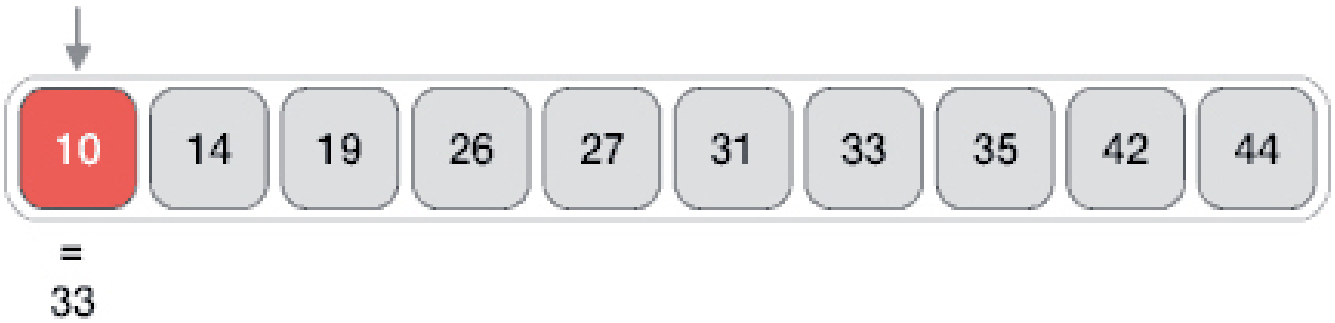
Look at each item in the list, one by one, from first to last, until the key is found.

- a sequential search is made over all items one by one
- every item is checked
- if a match is found, then index is returned
- otherwise the search continues until the end of the sequence

Example: search for the item with value 33

Linear search #2

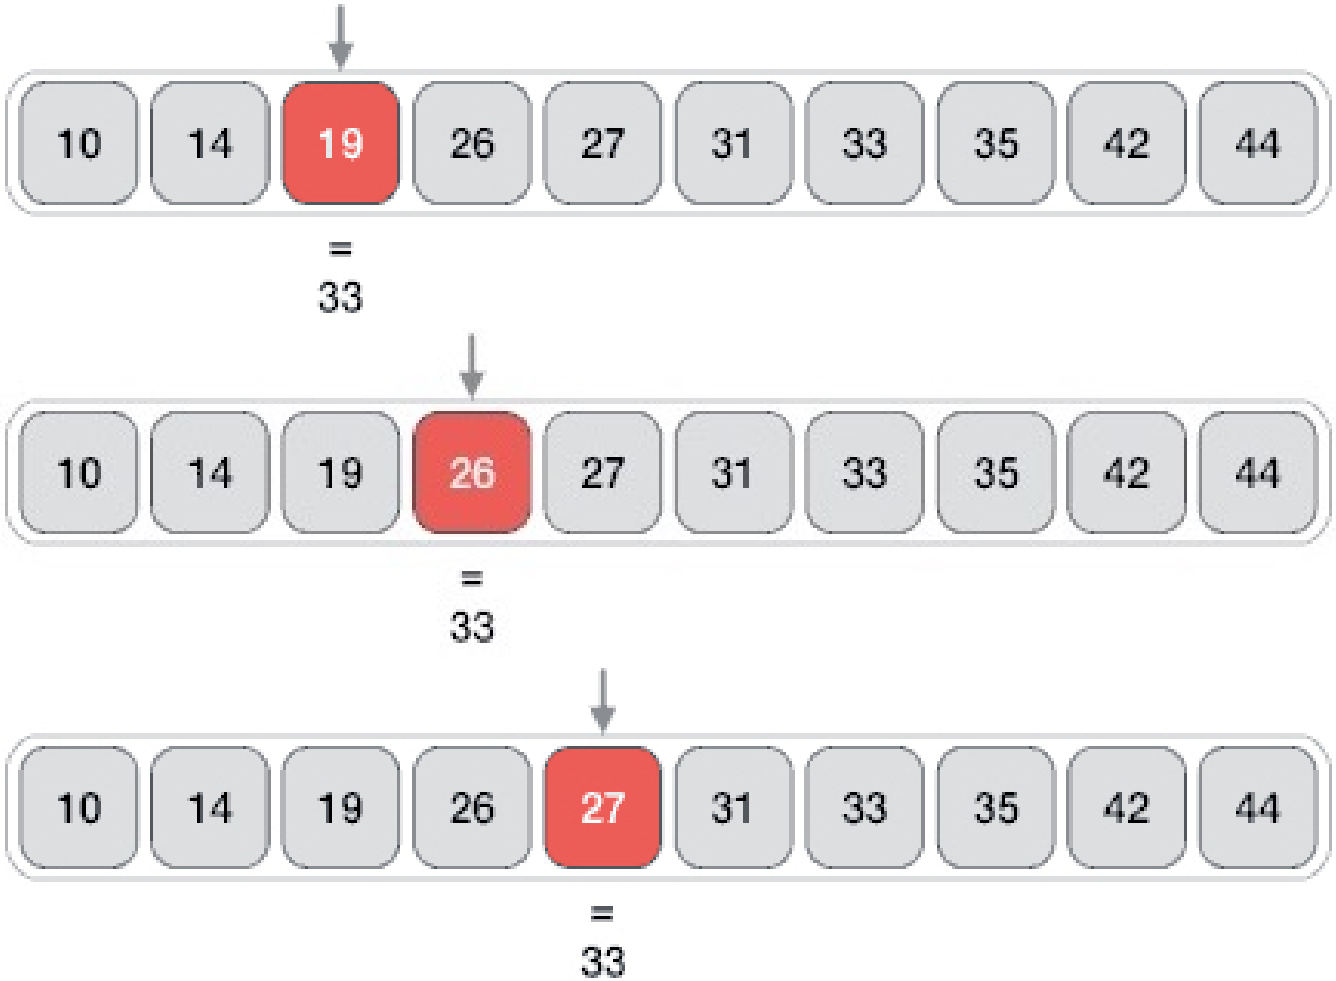
Starting with the first item in the sequence:



Then the next:

Linear search #3

And so on and so on...



Linear search #4

Until an item with a matching value is found:

If no item has a matching value, the search continues until the end of the sequence

Linear search: pseudocode

Algorithm 2 Linear search

```
1: procedure LINEAR_SEARCH(sequence, key)
2:     for index = 0 to length(sequence) do
3:         if sequence[index] == key then
4:             return index
5:         end if
6:     end for
7:     return None
8: end procedure
```

Linear search: Python implementation

```
1  def linear_search(sequence, key):
2      for index in range(0, len(sequence)):
3          if sequence[index] == key:
4              return index
5      return None
6
7  #import random
8  #L = random.sample(range(1,10**9),10**7)
9  #import time
10 #time_start = time.time()
11 #print(f"start: {time.asctime(time.localtime(time_start))}
12 #index = linear_search(L, -1)
13 #print(index)
14 #time_finish = time.time()
15 #print(f"end:   {time.asctime(time.localtime(time_finish))}
16 #print("time taken (seconds):", time_finish-time_start)
```

Issues with linear search

Running time: If the sequence to be searched is very long, the function will run for a long time.

Example: The list of all medical records in Quebec contains more than 8 Million elements!

Much of computer science is about designing *efficient* algorithms, that are able to yield a solution quickly even on large data sets.

See experimentation on Spyder (linear_vs_binary_search.py)...

Binary search

A faster search algorithm (compared to linear)

- the sequence of items must be sorted
- works on the principle of 'divide and conquer'

Analogy: Searching for a word (called the key) in an English dictionary.

To look for a particular word:

- Compare the word in the middle of the dictionary to the key
- If they match, you've found the word! Stop.
- If the middle word is greater than the key, then the key is searched for in the left half of the dictionary
- Otherwise, the key is searched for in the right half of the dictionary
- This repeated halves the portion of the dictionary that needs to be considered, until either the word is found, or we've narrowed it down to a portion that contains zero word, and we conclude that the key is not in the dictionary

Binary search #2

Example: let's search for the value 31 in the following sorted sequence

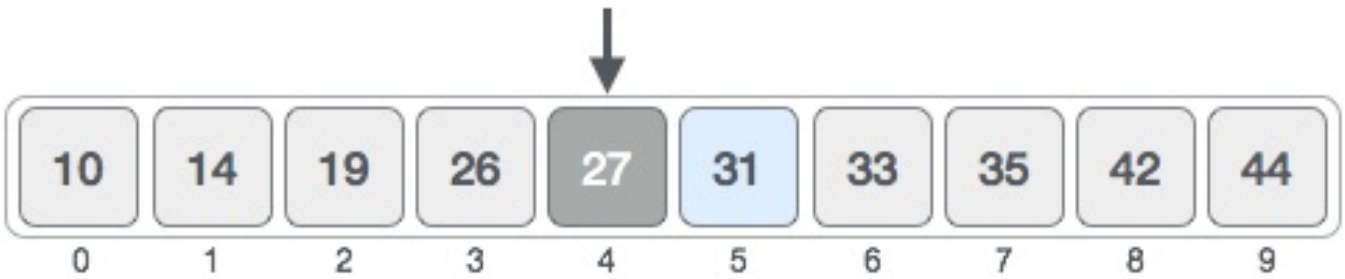
First, we need to determine the middle item:

```
1  sequence = [10, 14, 19, 26, 27, 31, 33, 35, 42, 44]
2  low = 0
3  high = len(sequence) - 1
4  mid = low + (high-low)//2     # integer division
5  print (mid) # prints: 4
```

Binary search #3

Since *index* = 4 is the midpoint of the sequence

- we compare the value stored (27)
- against the value being searched (31)



The value at index 4 is 27, which is not a match

- the value being search is greater than 27
- since we have a sorted array, we know that the target value can only be in the upper portion of the list

Binary search #4

low is changed to *mid* + 1

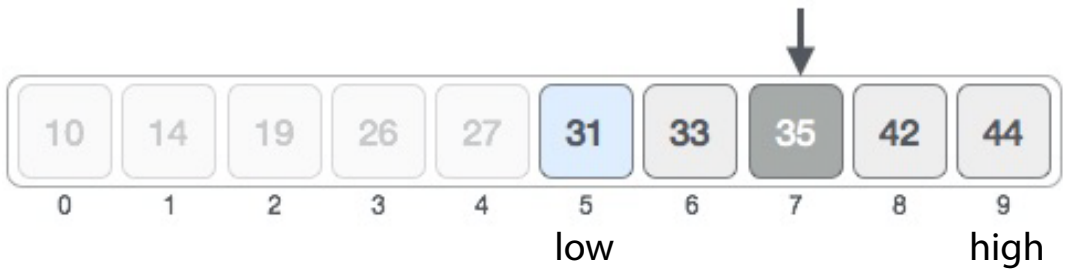
Now, we find the new *mid*

```
1 low = mid + 1    # 5
2 mid = low + (high-low)//2     # integer division
3 print (mid) # prints: 7
```

Binary search #4

mid is 7 now

- compare the value stored at index 7 with our value being searched (31)



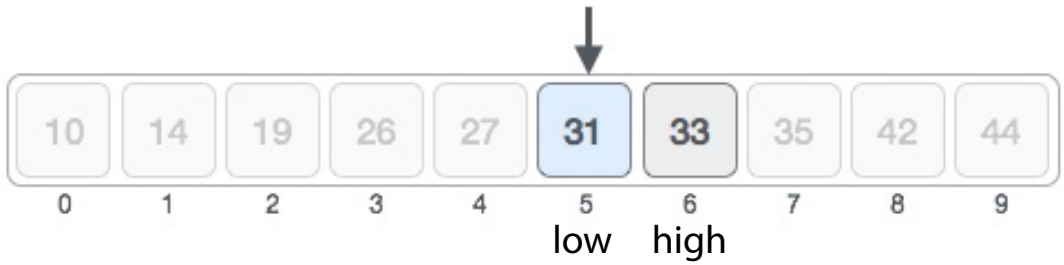
The value stored at location 7 is not a match

- 35 is greater than 31
- since it's a sorted list, the value must be in the lower half
- set *high* to *mid* - 1

Binary search #5

Calculate the mid again

- *mid* is now equal to 5



We compare the value stored at index 5 with our value being searched (31)

- It is a match!

Binary search #6

Remember,

- binary search halves the searchable items
- improves upon linear search, but...
- requires a sorted collection

Binary search: pseudocode

Algorithm 3 Binary search

```
1:  procedure BINARY_SEARCH(sequence, key)
2:      low = 0, high =length(sequence) − 1
3:      while low ≤ high do
4:          mid = (low + high) / 2
5:          if sequence[mid] > key then
6:              high = mid - 1
7:          else if sequence[mid] < key then
8:              low = mid + 1
9:          else
10:             return mid
11:         end if
12:     end while
13:     return 'Not found'
14: end procedure
```

Binary search: Python implementation

```
1  def binary_search(sequence, key):
2      low = 0
3      high = len(sequence) - 1
4      while low <= high:
5          mid = (low + high)//2
6          if sequence[mid] > key:
7              high = mid - 1
8          elif sequence[mid] < key:
9              low = mid + 1
10         else:
11             return mid
12     return None
```

Linear vs Binary search efficiency

Try linear_and_binary_search.py to see for yourself the difference in running time for large lists!

For a list of 10 Million elements:

- linear search takes about 3 seconds
- binary search takes about 0.0002 seconds.
- binary search is more than 100,000 times faster than linear search.

In general,

- the running time of linear search is proportional to the length of the list being searched.
- the running time of linear search is proportional to the **logarithm** of the length of the list being searched.

Binary search versus Linear search

```
1   import random
2   import time
3   from decimal import Decimal
4   from linear_search import linear_search
5   from binary_search import binary_search
6
7   # generate list of 10 Million elements,
8   # where each element is a random number between 0 and 1,000,000,000
9   print("Generating list...")
10  n = 10**7
11  L = random.sample(range(10**9), n)
12
13  L.append(111111111) # for testing purpose
14  L.append(555555555)
15  L.append(999999999)
16
17  print("Sorting list...")
18  L.sort()
19
20  while True:
21      key = int(input("Enter key for linear search: "))
22
23      # perform linear search
24      print("Starting linear search ...")
25      time_start = time.time()
26      index = linear_search(L, key)
27      time_finish = time.time()
28      linear_search_time = time_finish-time_start
29      print(f"Found at position: {index}; time taken:", \
30            "{:.2e}".format(linear_search_time), "seconds")
31
32      print("Starting binary search ...")
33      time_start = time.time()
34      index = binary_search(L, key)
```
